B. REPORTS

GEOCHEMISTRY OF THE REHOBOTH BASEMENT GRANITOIDS, SWA/NAMIBIA

G.F.U. Stoessel and U.R.F. Ziegler

KAW Laboratory for Isotope Geology, University of Berne, CH-3012 Berne, Switzerland

ABSTRACT

Geochemical analyses of 102 samples are reported from the 25 largest intrusive bodies of the Gamsberg, Piksteel and Weener Intrusive Suites within the Rehoboth basement inlier. It is shown that all the analysed granitoids are peraluminous and that they plot on calcalkaline differentiation trends. The high alumina saturation of most of the analysed samples suggests an upper crustal origin for most of the Gamsberg, Piksteel and Weener magmas.

1. INTRODUCTION

The large bodies of intrusive granitoids underlying the Rehoboth area of SWA/Namibia were first investigated by De Kock (1934). He described these granitoids as granites, diorites, quartz diorites and quartz porphyries which were derived from a common magma source. De Waal (1966) distinguished between the Nauchas Granite Suite which comprised the Gamsberg, Piksteel, Koepel and Korabis granites, a green granodiorite and the Weener Quartz Diorite. SACS (1980) renamed the Nauchas Granite Suite the 'Gamsberg Granite Suite', but excluded the Piksteel Granodiorite which was believed to belong to an earlier magmatic event.

The aim of this study is to provide more data on the geochemical relationships between the granitoids in the Rehoboth basement and to investigate the possibility of further subdividing these intrusives.

2. LITHOLOGY AND FIELD RELATIONS

2.1 Gamsberg Granite Suite

The Gamsberg Granite Suite, hereafter abbreviated to GGS, is made up predominantly of large plutons which have intruded both meta-volcanosedimentary formations, viz. the Mooirivier, Neuhof, Elim, Marienhof, Gaub Valley, Nückopf and Grauwater Formations, and older granitoids, viz. the Piksteel Intrusive Suite and the Weener Intrusive Suite. Smaller plutons of the GGS are irregularly distributed throughout the Rehoboth area.

U/Pb and Rb/Sr age determinations of the GGS have yielded a range of ages between 1 092 \pm 40 Ma and 1 210 Ma (Mailing, in prep.; Seifert, 1986a; Burger *et al.*, 1973, 1973-74, 1975-76), while Nückopf volcanics yielded ages between 1 080 Ma and 1 232 Ma (Burger *et al.*, 1973, 1973-74,1975-76).

Granites of the GGS are typically greyish to reddish

in colour, mostly medium- to coarse-grained and occasionally porphyritic. These granites further exhibit moderate alteration and saussuritization, sometimes with significant growth of muscovite and epidote. In the northern parts of the area, towards the southern margin of the Damara Orogen, the granites may develop a strong foliation together with widespread albitization of plagioclase and recrystallization of quartz.

2.2 Piksteel Intrusive Suite

In this report the term 'Piksteel Intrusive Suite' (PIS) is preferred to the term 'Piksteel Granodiorite' introduced by SACS (1980), since this unit comprises not only granodiorites but to a large extent also consists of granites and tonalites. Rocks of the PIS, first described by De Waal (1966), occur throughout the Rehoboth basement area and have intruded the Weener Intrusive Suite as well as the Mooirivier, Neuhof, Elim, Marienhof and Gaub Valley Formations. These granitoids have in turn been intruded by plutons of the GGS. U/Pb age determinations range between 1 430 Ma and 1630 Ma (Burger *et al.*, 1973-74 and 1975-76), while a single Rb/Sr isochron for the Swartmodder Granite of the PIS yielded an age of 1 660 Ma (Mailing, 1978).

Granitoids of the PIS are mostly greyish to greenish in colour, fine- to medium-grained and often porphyritic. They show wide compositional variation from granite through granodiorite to tonalite. In contrast to the GGS these granitoids exhibit widespread and pervasive saussuritization. A strong foliation, sometimes shear-related, is developed in the northern and eastern parts of the Rehoboth basement.

2.3 Weener Intrusive Suite

Tonalites, quartz diorites, diorites and granodiorites of the 'Weener Intrusive Suite' (WIS), previously termed

TABLE 1: Major and trace element analyses of the Gamsberg Granite Suite (no data recorded where concentration of trace element is below detection limit).

the 'Weener Quartz Diorite' (SACS, 1980), were first described by De Waal (1966). The granitoids of the WIS are confined to the western part of the Rehoboth area where they have intruded the Mooirivier, Elim and Gaub Valley Formations and have in turn been intruded by rocks of the PIS. The fine-to medium-grained rocks of the WIS are generally greyish to brownish in colour. Besides plagioclase, quartz, biotite and minor amounts of potassium feldspar, the occurrence of bluish amphiboles is distinctive. Accessory minerals include muscovite, sphene, opaque minerals, epidote, clinozoisite, garnet, apatite, chloritoid and chlorite (after biotite). As in the GGS and PIS, the granitoids of the WIS are locally strongly sheared and folded.

3. METHOD

A total of 102 samples with a mass of between 2 and 30 kg each was collected from the 25 largest intrusive bodies within the Rehoboth basement. Analyses of 11 major and 20 trace elements were carried out on a Philips PW1400 X-ray fluorescence spectrometer at the University of Fribourg, Switzerland (Tables 1-3). Loss on ignition was determined by heating of an aliquot of each sample for two hours at 1150 °C.

4. GEOCHEMISTRY

4.1 Gamsberg Granite Suite

The relatively linear patterns obtained in the Harker variation diagrams (Fig. 1) probably reflect original magmatic processes and suggest that the effect of postcooling alteration was minimal. Data for 55 samples were plotted on the R1 versus R2 diagram of De la Roche et al. (1980) in order to chemically classify members of this suite (Fig. 2). The vast majority of the data points fall within the 'granite' field with only a slight scatter of data points into the 'alkaline granite' and 'granodiorite' fields. According to Shand (1927) and Chappell and White (1974), the degree of alumina saturation allows a first order classification of granitoids. Accordingly, the data were plotted on a wt. % Al₂O₃-CaO-(Na₂O+K₂O) ternary diagram (Fig. 3), which illustrates that all samples have Al₂O₃ > (Na₂O+K₂O+CaO) and can, therefore, be classified as peraluminous. The generally high degree of alumina saturation for most of the Gamsberg granitoids is further illustrated in the mol. % Al₂O₃ versus mol. % (CaO+Na₂O+K₂O) diagram (Fig. 4) where the ratio A/CNK exceeds unity. However, the degree of alumina saturation is insufficient to classify these granitoids as S-type granites according to Chappell and

Nb11 Zr23 Y5 Sr16 Rb14 Th13 Pb16 Ga5 Zn18 Cu9 Ni12 Co3 Cr26 V26 Ce46 Nd26 Ba40 La44 Sc7 S216 White (1974) since the A/CNK ratio is generally less than 1,1.

On an AFM diagram of Kuno (1968), the data points of the GGS clearly define a calc-alkaline trend (Fig. 16). In the tectonic discriminant diagram of Pearce *et al.* (1984), the relatively low Rb, Nb and Y contents of these granitoids result in the majority being classified as 'Volcanic Arc Granites' (Fig. 5) However, since high alumina contents and low Nb and Y values are thought to be typical of crustal melt granitoids (Pearce *et al.*,

1984; McDermott, 1986), it can be proposed that the peraluminous Gamsberg Granite Suite represents I-type upper crustal melts. This proposal broadly coincides with the high ⁸⁷Sr/⁸⁶Sr initial value of 0,708 which has been reported by Reid *et al.* (1988). However, while the low ⁸⁷Sr/⁸⁶Sr initial ratios of between 0,700 and 0,702 reported by Seifert (1986a, b) confirm I-type magmatism for the GGS, they do not support an upper crustal source.

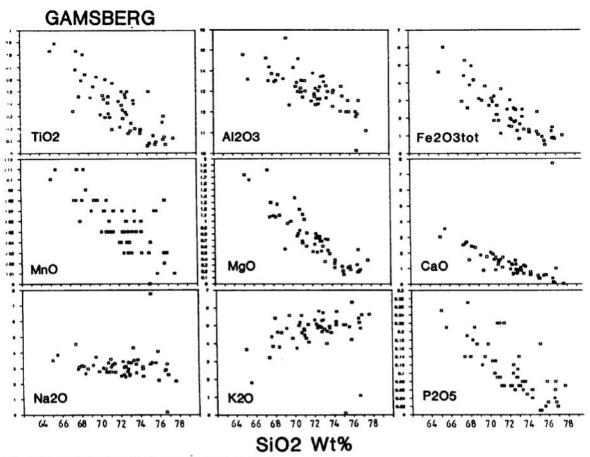

Fig. 1: Harker diagrams for the Gamsberg Granite Suite.

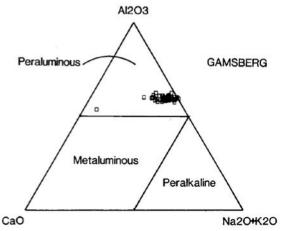

Fig. 3: Wt. % Al₂O₃-CaO-(Na₂O+K₂O) ternary diagram after Shand (1927) for the Gamsberg Granite Suite.

4.2 Piksteel Intrusive Suite

Linear data arrays for 36 Piksteel samples on Harker diagrams (Fig. 6) probably reflect magmatic processes. However, non-linear scatter of data points in plots of Na₂O and K₂O versus SiO₂ are most probably the result of post-intrusive alteration (saussuritization) processes. The diagram of De la Roche *et al.* (1980) illustrates that the PIS is made up largely of granodiorite with lesser

plutons of granite, alkali granite, diorite, quartz monzonite and tonalite (Fig. 7). All of these granitoids plot within the peraluminous field on a wt. % Al_2O_3 -CaO-(Na_2O+K_2O) diagram (Fig. 8). In the mol. % Al_2O_3 versus mol. % (Na_2O+K_2O+CaO) diagram (Fig. 9) the wide range of A/CNK values from less than 1,0 to greater than 1,4 contrasts markedly with the Gamsberg data. The strong alumina over saturation (A/CNK > 1,1) of many of the Piksteel samples suggests an S-type origin,

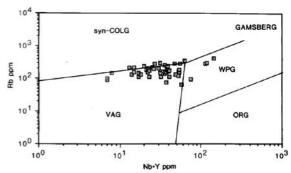

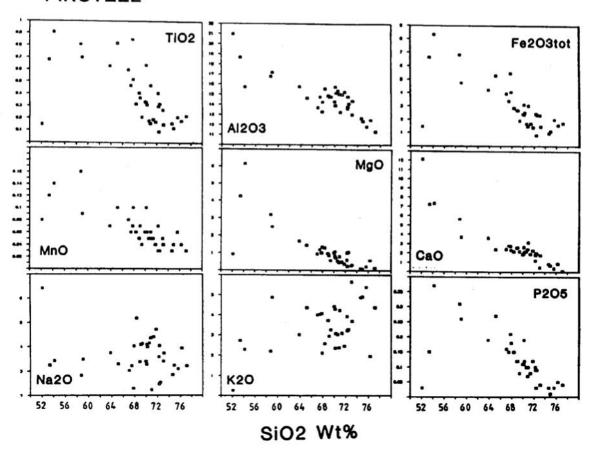

Fig. 5: Rb versus Nb+Y diagram after Pearce et al. (1984) for the Gamsberg Granite Suite (VAG = Volcanic Arc Granites; syn-COLG = syn-Collision Granites; WPG = Within Plate Granites; ORG = Ocean Ridge Granites).

Fig. 6: Harker diagrams for the Piksteel Intrusive Suite.

PIKSTEEL

while the few samples which plot below the A/CNK = 1,1 line are probably of I-type origin.

Again, the Piksteel samples which define a calc-alkaline trend in the AFM diagram of Kuno (1968, Fig.

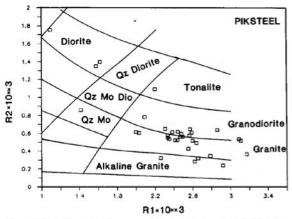

Fig. 7: Classification diagram of De la Roche et al. (1980) for the Piksteel Intrusive Suite (R1 = 6Ca+2Mg+Al: R2 = 4Si-11(Na+K)-2(Fe+Ti)).

16), are classified as 'Volcanic Arc Granite' according to Fig. 10. Also here the low contents of Rb, Nb and Y and the peraluminous nature are indicative of an upper crustal origin. A crustal origin is supported by the high initial ⁸⁷Sr/⁸⁶Sr ratios for Piksteel intrusives obtained by Reid *et al.* (1988) which range between 0,707 and 0,709. Insufficient geochemical data exists at present to allow an overall genetic interpretation.

However, detailed work on single intrusions and the application of isotope geochemistry will enable us to elucidate the genetic relationships between the different members of the PIS.

4.3 Weener Intrusive Suite

A total of 12 samples was collected from the three largest bodies of the WIS. Despite plotting on similar differentiation trends in Harker diagrams (Fig. 11), the data points can be grouped together on a regional basis. The WIS is made up of granite, granodiorite, tonalite, diorite and gabbro as indicated by the diagram of De la Roche *et al.* (1980; Fig. 12). As for the GGS and PIS, all the Weener samples are peraluminous according to a wt. % Al₂O₃-CaO-(Na₂O+K₂O) plot (Fig. 13). However, A/CNK ratios of the WIS are, although being within the range of the PIS, notably higher than those of the GGS and the major part of the PIS (Fig. 14). A/CNK ratios above 1,1 indicate an S-type origin for the Weener rocks according to the criteria of Chappell and White (1974).

An S-type origin is supported by the low Rb, Nb and Y contents which classify these granitoids as 'Volcanic Arc Granites' (Fig. 15) according to Pearce *et al.* (1984), but is in contradiction to the relatively low ⁸⁷Sr/⁸⁶Sr values of 0,700-0,705 reported for the WIS by Seifert (1986a, b) and Reid *et al.* (1988).

5. SUMMARY

All the analysed samples of granitoids from the Rehoboth basement area are peraluminous according to the criteria of Shand (1927) and Chappell and White (1974). The GGS, PIS and WIS are calc-alkaline in character according to the AFM diagram of Kuno (1968; Fig. 16). A/CNK ratios indicate an S-type origin for the Weener granitoids, an S- or I-type origin for the Piksteel granitoids and an I-type origin for the Gamsberg granitoids. These results only partly coincide with isotopic data of Reid *et al.* (1988) and Seifert (1986a, b) which favour I-type origins for almost all of the Rehoboth granitoids. However, the high alumina saturation of most of the analysed samples suggests that the vast majority of the granitoids in the Rehoboth basement inlier are derived from upper crustal melts.

6. ACKNOWLEDGEMENTS

This study is being carried out as part of a University

Research Project sponsored by the Geological Survey of SWA/Namibia. We wish to thank Prof. E. Jäger and Dr. R.McG. Miller for supervising the project and D. Vuichard for his kind help in getting the XRF system going. A first manuscript was kindly reviewed and corrected by B. Hoal of the Geological Survey.
