**SYNOPSIS.** An examination of scalation and dentition of specimens in Brussels (IRSN), Tervuren (MRAC) – mostly Bredo collection, and London (BMNH) from Angola, Congo-Kinshasa and Zambia suggests the existence of a species which is neither *P. sibilans leopardinus* of which the type is from Namibia, nor *P. 'sibilans' /mossambicus* of Congo-Kinshasa and Zambia, but a new species previously unnamed.

## INTRODUCTION

Bocage (1887:206) described from Catumbela, Angola a *Psammophis* (MBL 1798, now destroyed) with a striking reticular pattern on the neck and anterior part of the body as a variety of *Psammophis sibilans*, a taxonomic treatment later followed by Broadley (1977). More recently Brandstätter (1995, 1996: Fig. 4) has recognised *P. sibilans* as occurring no further south than the northern part of Tanzania and has treated Bocage's variety as *P. brevirostris leopardinus*, following an earlier practice by Broadley (1971). He has followed Broadley (op. cit.) in assigning to this subspecies Zambian specimens showing the same reticular pattern on the neck. However, such a pattern occurs sporadically elsewhere, as in West African specimens of *P. sibilans* (BMNH 1930.6.5.8 from Mogonori, Ghana; 1956.1.5.87 from Ikoyi, Lagos, Nigeria; CM 24636 from Accra; MNHN 1985.442–3 from Ghana; ZMH R04466 from Gana Gana or Segbana, Niger Delta, Nigeria: these have neck bars sometimes interconnected as in *leopardinus*. Dependence on pattern for identification in a genus whose species are notorious for their variability is unconvincing. In an attempt to find other, more reliable criteria by which to distinguish species of *Psammophis*, total tooth counts were undertaken and revealed significant differences between specimens of '*leopardinus*' from Angola and those from Zambia. Secondly, the Zambian specimens are often of a colour pattern rarely met with elsewhere during the study of several thousand specimens from all parts of Africa and the Middle East. Thirdly, the ventral and subcaudal counts of the Zambian specimens are lower than those from neighbouring localities in Zambia and Congo-Kinshasa. Fourthly, a SEM micrograph of a dorsal scale of a specimen from Ikelenge (Brandstätter, 1995: Fig. 39) differs considerably from those of species assigned to the *P. sibilans* complex. For these reasons, it is thought necessary to coin a new name for the Zambian specimens.

## SYSTEMATICS

*Psammophis zambiensis* sp. nov.      Zambian Whip Snake

*Psammophis sibilans*, not Linnaeus 1758, Pitman, 1934: 297 (part, Chimikombe specimens only).

*Dromophis lineatus*, not Dumeril & Bibron, Laurent 1956:247  
Kundelungu male & female.

*Psammophis ? sibilans* Broadley & Pitman 1960: 445

*Psammophis brevirostris leopardinus* Broadley 1971:88;  
Brandstätter, 1995: 53, Fig. 39 and 1996: 48 (Zambian specimens  
only); Haagner et al. 2000:16.

*Psammophis sibilans leopardinus* (Zambian specimens) Broadley  
1977:18

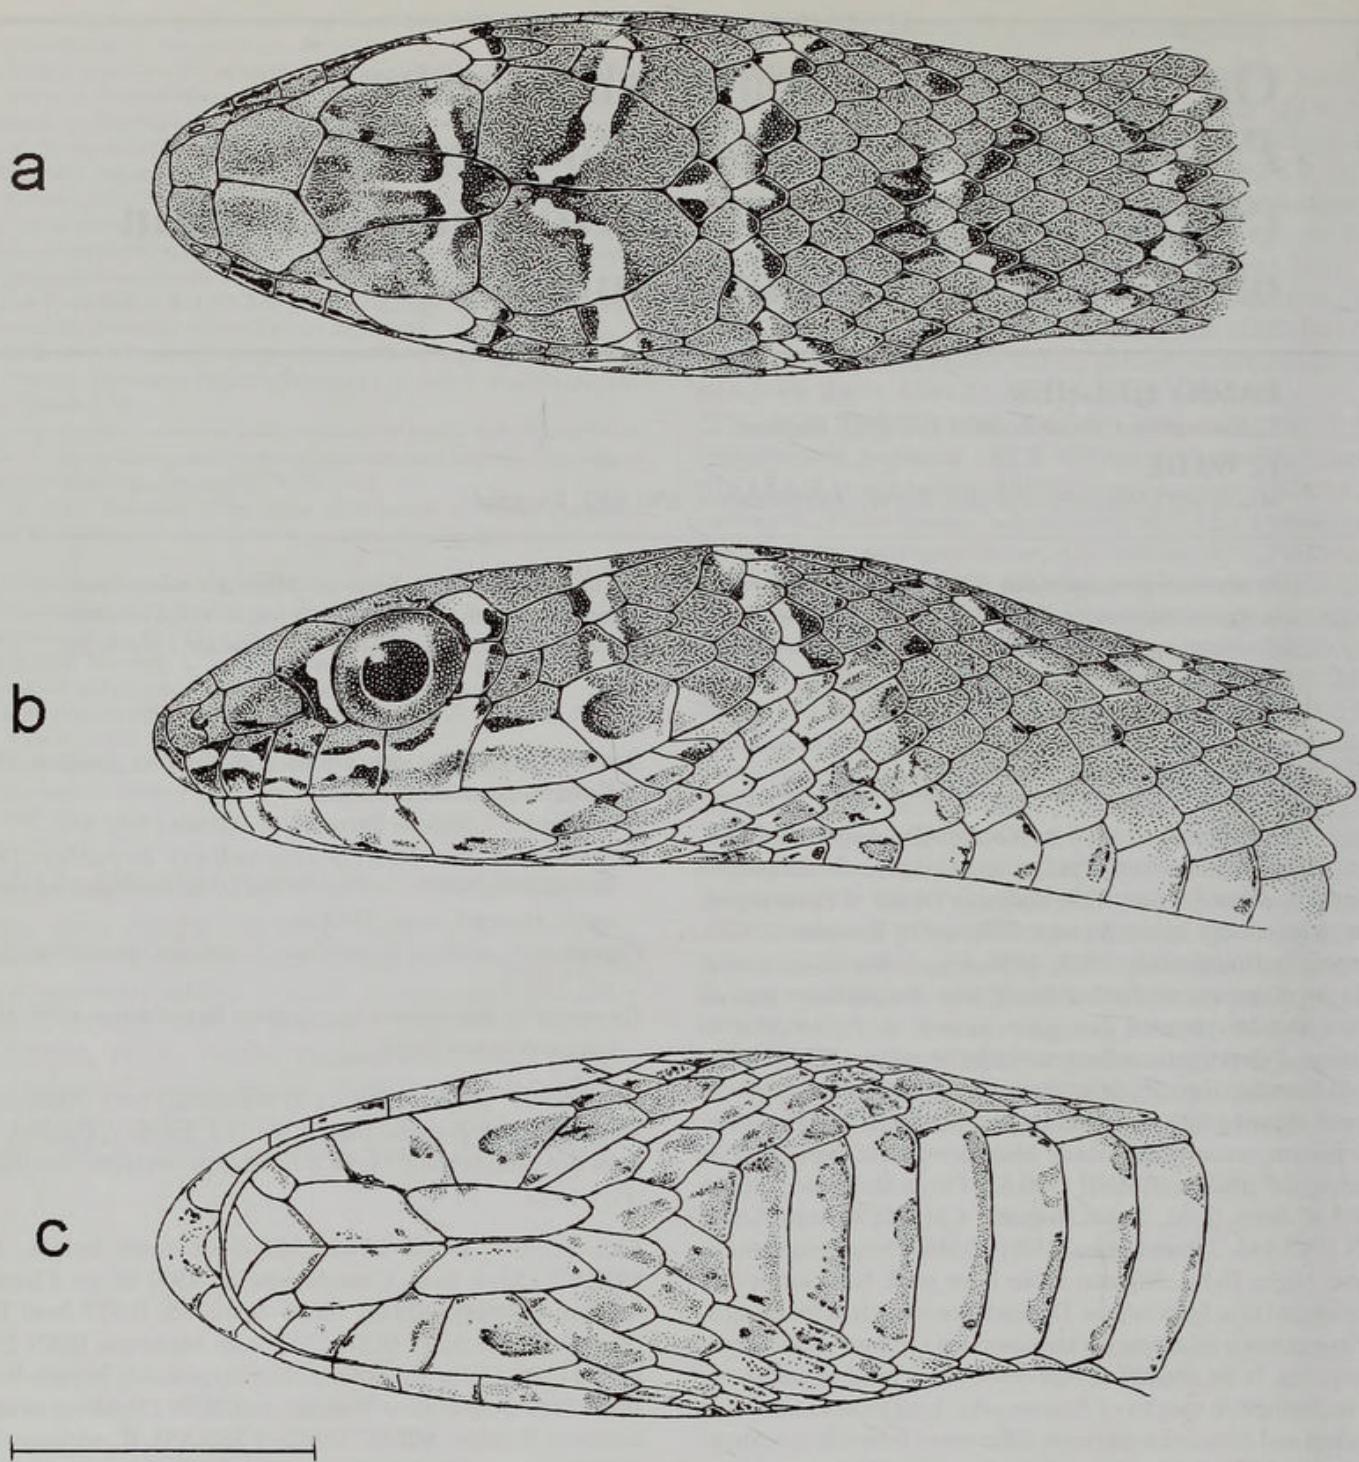

*Psammophis brevirostris leopardinus* Brandstätter 1996:48 (Zam-  
bian specimens only)

**HOLOTYPE.** BMNH 1959.1.1.81 supposedly from 'Abercorn' (now Mbala) area of Zambia, part of the H.J. Bredo collection, sent on from Brussels, but likely to be from Mweru-Wantipa – see discussion (Figs 1–3).

**PARATYPES.** IRSN 2561,2565–6 of same origin, BMNH 1932.9.9.132–3 from Chimikombe at 4500 ft. (= Chimilombe, Solwezi District); NMZB 10635–6, 10736, 10757 from Ikelenge (Broadley 1991:529); IRSN 2562 from Mambwe; IRSN 2567 and PEM 1438/12 from Mporokoso District (probably Mweru-Wantipa); IRSN 2563 from Mweru-Wantipa, and IRSN 2564 from an unknown source in Zambia; MRAC 18622–3 SERAM, Kundelungu Plateau 1750 m, Congo-Kinshasa (Laurent 1956:247 as *Dromophis lineatus*).

All specimens, except two (BMNH 1932.9.9.132–3) are female; Haagner et al (2000) have listed two more males as '*P. brevirostris leopardinus*'.

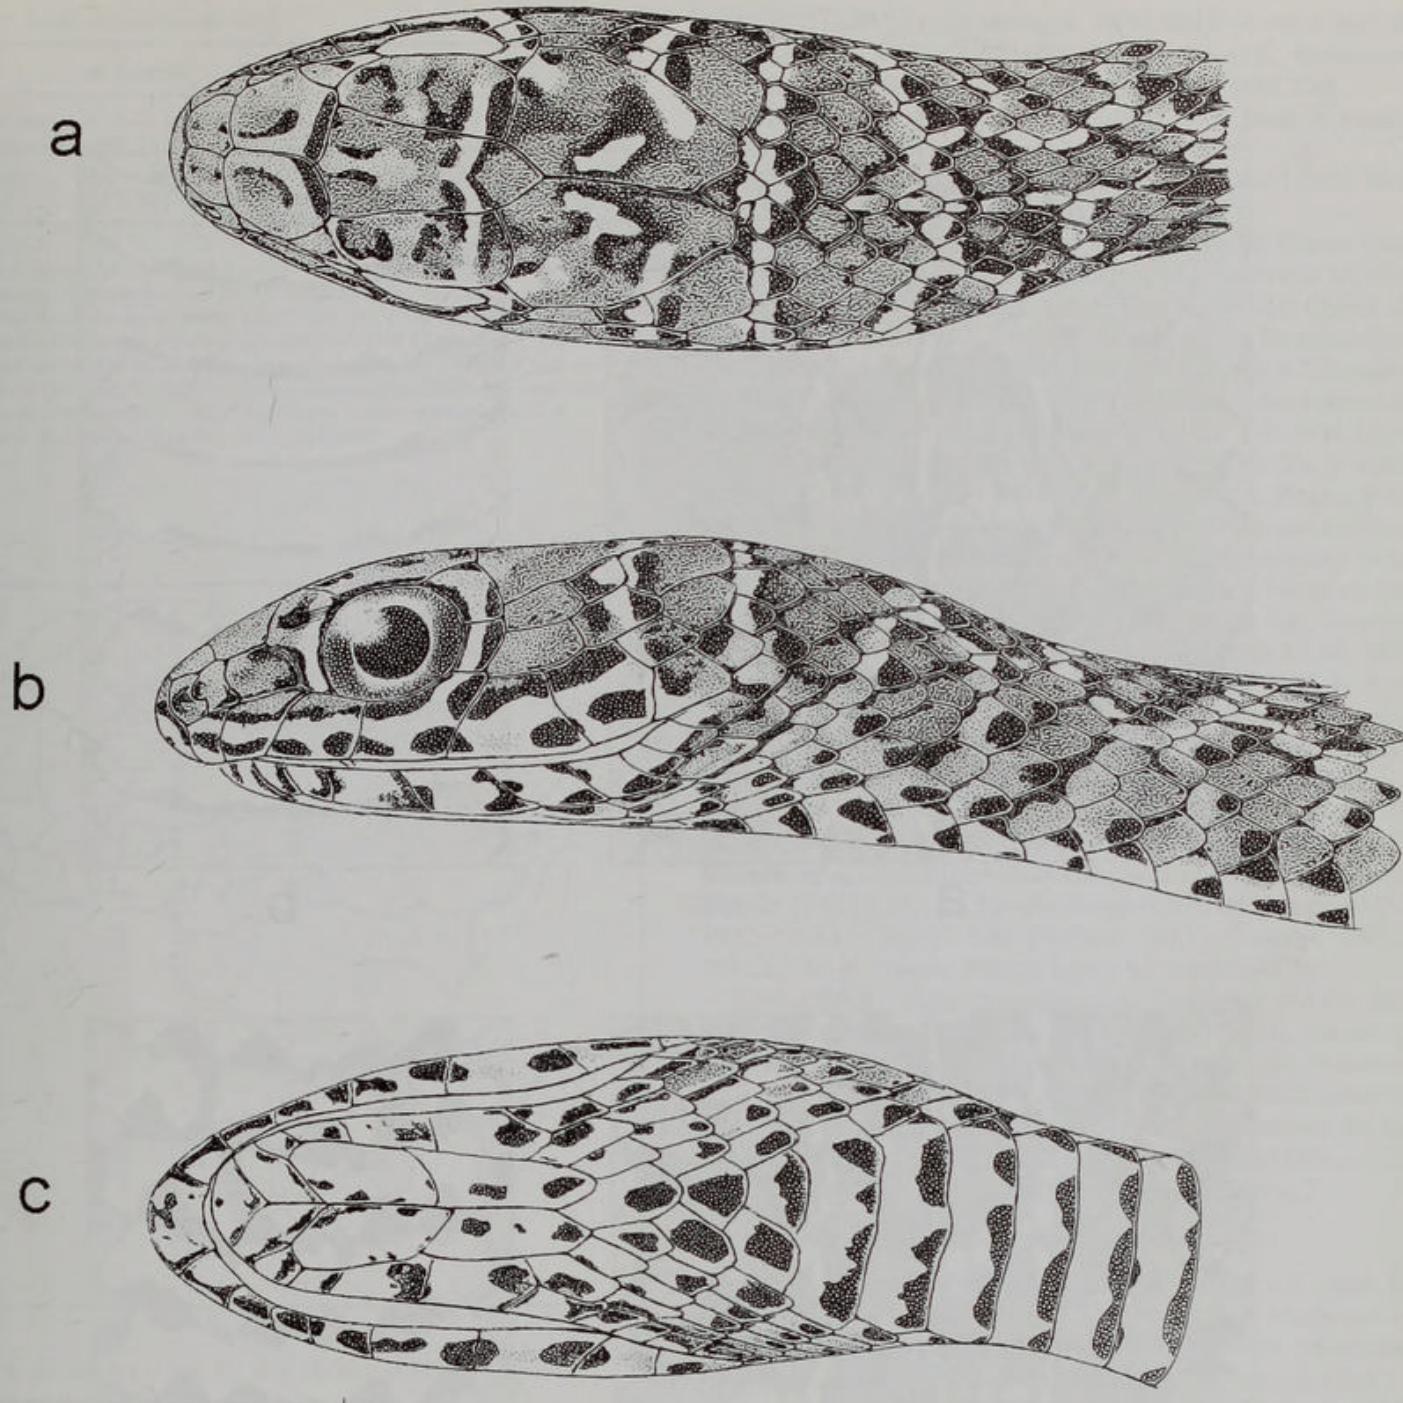

**DIAGNOSIS.** Often distinguished by a combination of the reticular body pattern of *leopardinus* but lacking the higher tooth counts of the latter (Table 1.). A detailed description of colouration, based on 5 specimens, is given by Broadley & Pitman (1960:445) but can be summed up by saying that they are greenish rather than the usual khaki-brown and the scales heavily edged in black. Unlike associated specimens of *P. 'sibilans'* the vertebral 'chain' is more like a stripe, the lighter marking on each vertebral scale being more of a line than a spot; and behind the eyes the head is crossed by three transverse light bars – a common feature in many *Psammophis* spp. but these are narrow, as in *P. angolensis* or *Dromophis lineatus*. Smaller specimens (e.g. Fig. 2–3) are more distinctly marked with greater contrast around the body. As Haagner et al (2000) have

**Fig. 1** Head of *P. zambiensis* (adult holotype, BMNH 1959.1.1.81) seen in (a) dorsal, (b) lateral and (c) ventral views.

**Table 1** Dentitions – left/right sides.

<i>leopardinus</i> (Namibia)	1937.12.3.166	5/5	23/24	11/9	23/18
<i>zambiensis</i>	1959.1.1.81	4/3	17/14	9/8	17/14
<i>zambiensis</i>	10636	-/3	14/13	8/9	13/12
<i>zambiensis</i>	10736	4/4	15/14	8/9	16/15
<i>zambiensis</i>	10521	3/3	15/15	8/8	16/16
<i>zambiensis</i>	10522	3/3	13/-	9/8	15/14
<i>zambiensis</i>	10523				
<i>zambiensis</i>	18622	3/3	16/16	7/8	14/15
<i>zambiensis</i>	18623	4/4	17/15	8/9	17/18
<i>zambiensis</i>	1932.9.9.132	3/3	17/19	9/9	17/16
<i>zambiensis</i>	1932.9.9.133	3/3	20/20	8/8	19/18
<i>zambiensis</i>	1953.1.2.15	3/3	17/18	8/8	18/18
<i>sibilans</i>	1953.1.2.14	3/3	19/18	8/8	16/15?

**Fig. 2** Head of juvenile paratype *P.zambiensis* (IRSN 10523) seen in (a) dorsal, (b) lateral, and (c) ventral views.

noticed, the reticular neck pattern is not always present and these specimens are distinguished from ‘*sibilans*’ by their lower ventral counts and usually by lower subcaudal counts (Table 2).

Brandstatter (1995: Fig. 39) has provided a SEM micrograph of a dorsal scale from a *P. zambiensis* paratype NMZB 10636, and the micro-ornamentation resembles that of *Dromophis lineatus* (his Fig. 83) more than any species of the *P. sibilans* complex.

**HABITAT.** Unfortunately, no field notes are available for this species, but the fact that many specimens appear to have originated from the Mweru-Wantipa suggests that it requires a marshy habitat like *Dromophis lineatus*, with which it is sympatric in this area (Broadley & Pitman, 1959). In the Ikelenge area there are many suitable dambos and one local specimen had eaten an *Eumecia anchietae*, a large skink that frequents such places (Broadley, 1991). The

Sanolumba snake had eaten a ranid frog (Haagner *et al.*, 2000).

#### OTHER SPECIES AND SOURCES OF DATA

*Psammophis leopardinus* [only those with numbers seen by BH, those without numbers DGB data or from publications].

ANGOLA – Bella Vista MCZ; Caconda MBL × 8; Capelongo AMNH × 6; Catengue SMF × 2; Catumbela MBL lectotype, destroyed; Iona TM; Luanda USNM; Lobito Bay AMNH R50612–3, R50617–8, and x5; Oncocua, 37 km NE on way to Otchinzau TM; NAMIBIA – Swakop-Tal, Namib Desert BMNH 1937.12.3.166.

*Psammophis ‘sibilans’*, currently treated as *P. mossambicus*.

CONGO-KINSHASA – Kambore MRAC 2017; Kansenia MRAC 7002, 7639; Kapanza MRAC 9649–50; Kapiri MRAC 7027, 7056–

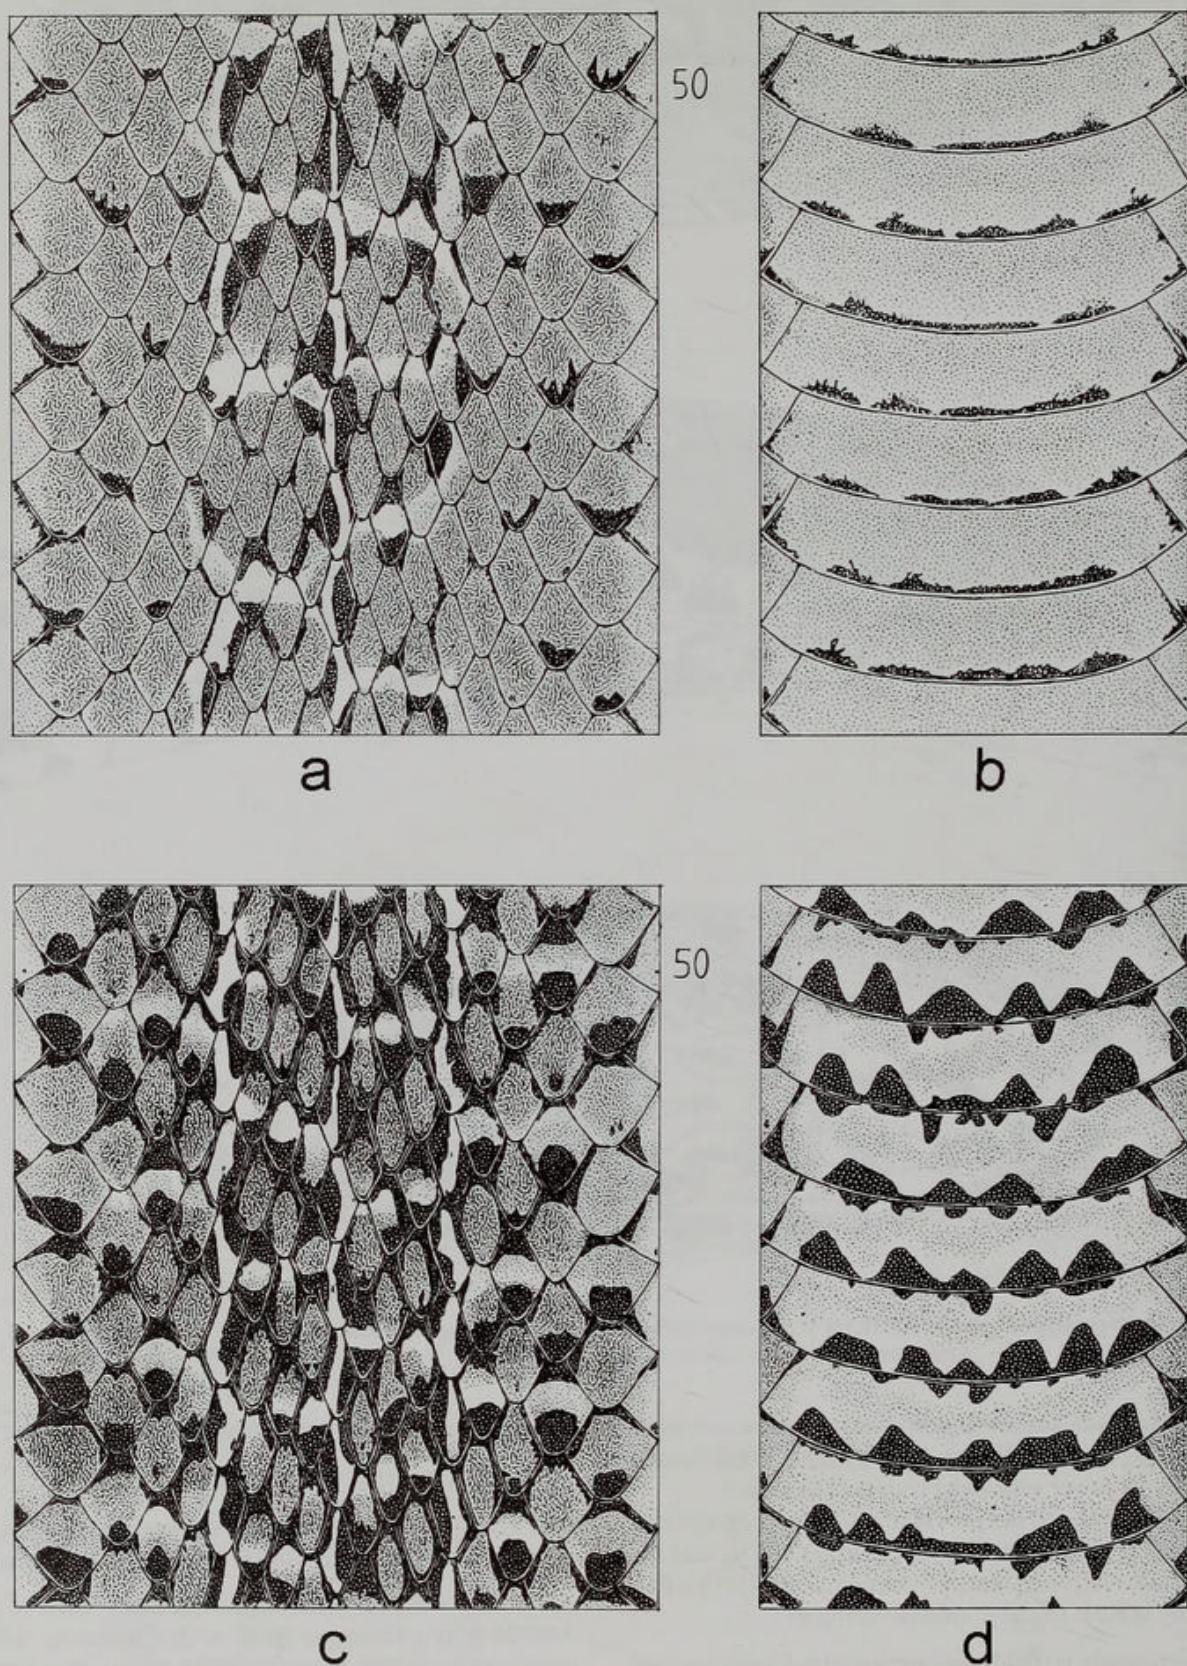

Fig. 3 Stretches of the body of *P.zambiensis* between ventral scales 50 and 57 seen in dorsal and ventral views. (a, b) Adult holotype (BMNH 1959.1.1.81); (c,d) juvenile paratype (IRSN 10523).

**Table 2** Scale counts (sample size)

species	M ventrals	F ventrals	M subc.	F subc.
'leopardinus'	151–71 (9)	151–74 (20)	79–104 (4)	80–105 (10)
'leop.' refined	151–65 (8)	151–67 (16)	79–104 (4)	80–105 (8)
<i>zambiensis</i>	148–61 (5)	149–65 (17)	80–90 (3)	75–86 (9)
'sibilans'	167–77 (32)	167–77 (19)	89–103 (26)	781–100 (12)

N.B. The *P. 'leopardinus'* data is for Angolan specimens and from Broadley (pers. com.); I suspect that specimens of another species are included and *P. 'leop. refined'* has the data of that species removed. The *P. 'sibilans'* (currently treated as *P. mossambicus*) data is from Zambian specimens so called by Broadley (1971:88) although he has since referred them to *P. phillipsi* (Broadley 1983) and later *P. mossambicus* (Broadley, in prep.), and from Haagner et al (2000) who treat their specimens as *P. mossambicus*. The *P. zambiensis* data incorporates that of *P. 'brevirostris leopardinus'* from Haagner et al. (2000).

## DISCUSSION

The many names by which Zambian *P. 'sibilans'* has been known (see above under synonymy) is an indication of the uncertainty which attends identification of specimens of this species complex. The very distinctive colouration of some specimens of *P. zambiensis* attracts attention but it is not reliable in separating this species from other(s) with which it may be sympatric. A letter from Desmond Vesey-FitzGerald to Donald G. Broadley (Broadley, pers. comm.), dated 29 Sept. 1959, suggests that the source of 'Abercorn' specimens is to be doubted: 'I would guess that all these snakes may have come from Mweru–Wantipa in Mporokoso District, where Bredo would have been collecting in the 1943/44 period.' Vesey-FitzGerald (1958) collected long series of *P. sibilans* [= *P. mossambicus*] in

**Fig. 5** Map of area of sympatry between *P. 'sibilans'* (○, literature ref. which may include *zambiensis*), ● specimen seen by BH or DGB and *P. zambiensis* (▲ specimens seen). Many records taken from Broadley (1983:146, map 36 of *P. 'phillipsii'*, others from an as yet unpublished, revised map (DGB in prep.) which we have been privileged to see. Localities listed by country and quarter degree square (without 'se' prefix); sources indicated when locality is a map plot without name. For locality data see Appendix 1.

Abercorn [= Mbala] District, but none had either the characteristic pattern or low ventral counts of *P. zambiensis*. However, he did record one snake from Chinsali (10.32 C1) with only 160 ventrals and 90 subcaudals, which may have been a *P. zambiensis*, but it was apparently not preserved. Only by collecting data on a large number of specimens can the limits of variability become known and consistent differences in meristic data become apparent.

*P. zambiensis* and *P. 'sibilans'* appear to be sympatric at Mbala (Abercorn) (Fig. 3, se08.31C4) but all of the *P. zambiensis* specimens so attributed are likely from Mweru-Wantipa (see above), so that true sympatry may occur only at Mporokoso (se09.30), Ikelenge (se11.24a2) Serenje (se13.3061) and near Mchinji (13.32d4). The co-occurrence over such a large distance – more than 600 km from Ikelenge to Mweru Wantipa without more instances of sympatry suggests the occupation of different habitats.

*P. zambiensis* seems to be distinct from *P. leopardinus* to the south and *P. 'sibilans'* (or '*phillipsi*') to the north; the true identity of the

latter can become clearer only after analysis of specimens from the whole of the Congo Basin and West Africa.

**ACKNOWLEDGEMENTS.** We are indebted to Donald Broadley for his usual generosity with his data and advice and for the loan of specimens; to curators Charles Myers and Richard Zweifel (AMNH), Georges Lenglet (IRSN, Brussels), Danny Meirte (MRAC, Tervuren), Rainer Günther (ZMB), and Colin McCarthy (BMNH) for similar loans and providing one or both of us with working space and answering our many queries.
